To evaluate the clinical efficacy of 810 nm diode laser combined with 532 nm fractional photorefractive keratectomy (FSRK) for the correction of astigmatism. Twenty-one patients with myopic astigmatism underwent diode laser combined with FSRK. The average preoperative uncorrected visual acuity was 0.37 +/- 0.20 and the mean corrected visual acuity was 0.76 +/- 0.17. The average keratometry was 43.92 +/- 2.57 D, the average corneal cylinder was -2.98 +/- 1.32 D and the average estimated astigmatism was -0.66 +/- 0.70 D. All eyes were followed up for 12 months postoperatively. Preoperative corneal topography demonstrated an average corneal astigmatism of -0.50 +/- 0.69 D, an average cylinder of -0.74 +/- 0.49 D and the average total astigmatism of -1.24 +/- 0.88 D. Postoperative astigmatism was -0.64 +/- 0.64 D at 1 month, -0.50 +/- 0.53 D at 3 months, -0.45 +/- 0.64 D at 6 months, and -0.28 +/- 0.35 D at 12 months. All eyes gained satisfactory visual acuity. The mean uncorrected visual acuity improved from 0.37 +/- 0.20 preoperatively to 0.60 +/- 0.15 at 12 months postoperatively (P = 0.009). The mean refractive astigmatism decreased 2d92ce491b
