My blog for the Institute of Personality and Social Research Menu Can you think on your feet when you are put under stress? In this study, people were shown pictures of their first-grade children, and then asked to answer questions about them. Under some conditions, those who were initially shown the picture of a happy child and asked questions about their current happiness answered questions correctly. However, when they were shown pictures of unhappy children, some of the adults became quite upset and their brain activity began to change. “At this point, something quite unusual happens: under stress, in contrast to most other species, the activity of the human frontal lobe goes down – not up.” According to Dr. Nick Fox, a researcher at the Institute of Psychiatry at King’s College London who worked on the study, “Our research shows that the brain’s ability to generate plans and make decisions for the future is the same as it is when you are relaxed and enjoying yourself. However, when the brain is under stress, the frontal lobes are much less capable of generating plans and making decisions – this is when you experience a loss of control.” While the people in the study may have all been adults, and may have simply been in a stressful situation, “Perhaps the most surprising thing about our results is that even though you might not think that you are able to act consciously when your attention is distracted and you are under stress, you can still generate cognitive action.” According to Dr. Fox, “Our research indicates that under stress, the brain is less able to generate plans and make decisions for the future. While it is not possible to directly observe the brain in action, our findings suggest that the brain of someone who is in a difficult situation is less able to plan and make decisions in advance. This is a problem because we need our ability to plan for the future to be able to cope with the challenges that life inevitably throws at us.” In a synchronous optical networking (SONET) system, a traffic channel is established between a terminal equipment and a network element to provide a common transmission medium for the exchange of data. Traffic channels are normally referred to as "virtual circuits" (VCs). Multiplexing techniques are applied to a data stream at the network element so that the data can be distributed to several VCs. Such distribution 2d92ce491b
