Interaction of ATP with thrombin and heparin in the activation of factor VII: evidence for the involvement of a novel ATPase. In this study, we examined the effect of ATP on the activation of factor VII (fVII) by thrombin and heparin. The activation of fVII by thrombin in the presence of heparin was dose- and time-dependent. In the absence of ATP, the activation of fVII by thrombin was only slight. However, the presence of ATP markedly enhanced thrombin-induced fVII activation. The effect of ATP on the activation of fVII by thrombin was not affected by the removal of heparin. When the amount of fVII that was activated by thrombin alone was subtracted from that obtained when thrombin was incubated with ATP and heparin, it became evident that ATP alone had a slight effect on the activation of fVII by thrombin. On the other hand, the activation of fVII by heparin in the presence of ATP was dose- and time-dependent. In the presence of ATP, the activation of fVII by heparin was substantially enhanced by the addition of thrombin, and the degree of enhancement of fVII activation was enhanced as the concentration of ATP was increased. Since fVII activation by both thrombin and heparin was inhibited by N,N'-dicyclohexylcarbodiimide (DCCD), the ATPase in the cell membrane is probably the same 2d92ce491b
