Today, a variety of materials are dispensed, sprayed, and/or otherwise applied to an intended application area. The materials, for example, can be in the form of powders, granules, liquids, liquids with solids, gels, liquids containing solids, etc. When spraying and/or applying one or more of these materials, a discharge source is often used. The discharge source often includes one or more piezoelectric elements that discharge one or more materials through a nozzle of the discharge source. Piezoelectric elements can be activated or deactivated by an electrical pulse to discharge a material out of the discharge source through the nozzle. Piezoelectric elements, for example, are commonly activated when a voltage, such as a pulse voltage, is applied to the piezoelectric element. Deactivation of a piezoelectric element includes applying an inverse voltage, such as an impulse voltage, to the piezoelectric element to recharge the piezoelectric element and to stop the piezoelectric element from discharging. To discharge a material from a discharge source, a piezoelectric element of the discharge source can be activated using an electrical pulse. Often, a conventional capacitor is used to supply the electrical pulse to the piezoelectric element. However, when a piezoelectric element of a conventional piezoelectric dispenser is activated, a relatively large voltage spike is often produced at the output of the conventional capacitor. The voltage spike is often high enough to cause the internal circuitry of a piezoelectric dispenser to malfunction. Additionally, the large voltage spike can damage the piezoelectric element.
