Among its other features, CMAT provides the possibility to enable trace on the heap, so you can analyze the stack of each running thread. It provides also the possibility to enable heap dump with /heapdump. However, heap dump is stopped by default because it is a very large amount of information. The major limitation of CMAT is that it doesn't provide a garbage collector. So, you need to have the proper understanding of how the memory works and be willing to spend a good part of your time to understand how the memory management takes place in a Windows O/S. If you don't like having to do the required steps then this might be a handy tool for you. I couldn't help but notice that it requires VTK and the MS Visual C++ compiler suite to compile. All in all, I think it is a nifty little tool and would be glad to see more developers building useful programs like this. Only question posters or moderators may add a new answer to this question. One thing that this tool cannot do is to specify custom ranges (websites, local or network drives,...) for the list of paths, but maybe someone can write a simple in-process tool with at least the same functionality, which is surely faster than a call to `get_executable_paths`.
